

Adult income: cross-entropy on the least represented race, Other (1 of 100 groups, 30 samples; the uniform-over-races target gives it $p_i = 0.2$)
 $K = 3$ groups observed per step, $H = 5$ local steps, 4000 steps; mean $\pm$ std of the last 500 steps over 5 seeds; lower is better

observation rate $r \propto p^\beta$, from aligned with the target ($\beta = 1$, feasible) to uniform, i.e. prevalence ($\beta = 0$); ν = infeasible mass
